

AI Business OS

Business Model & Product Specification

1. What This Business Is

AI Business OS is a subscription web platform that gives small and medium-sized businesses (SMEs) an AI-powered "operating system" for marketing and business operations — replacing the need to stitch together five or six separate tools (a CRM, an SEO tool, a design tool, a proposal template, an HR policy library, a BI dashboard) with one connected platform.

The customer answers a short onboarding questionnaire and connects a few existing tools (their website, Google Analytics, social accounts). From that point on, an AI layer generates marketing plans, proposals, SEO recommendations, and social content that are specific to their business — not generic templates — because the platform knows their industry, goals, competitors, and brand voice.

One-line pitch: *"Everything a small business needs to plan, market, and grow — powered by AI, in one dashboard, for one monthly subscription."*

2. Who It's For

Target market: **Businesses of all sizes — SMEs through mid-size and large companies — in Oman and the wider GCC, with room to expand beyond the region over time.** (Open for discussion)

Priority given first to industries the founder already has direct relationships with through an existing marketing agency and corporate network (construction, retail, professional services, and similar verticals), while the platform is built to also serve larger organizations from the outset.

Why this platform works across company sizes

- Smaller businesses can't justify hiring a full marketing team or paying enterprise SaaS prices, but still need marketing strategy, content, CRM, and reporting — this platform gives them all of it in one subscription.
- Larger organizations benefit from the same AI-generated strategy, proposal, and lead-generation tools, plus the full CRM and integration set, without needing to assemble and manage six separate enterprise vendors.
- Most competing AI marketing tools (HubSpot, Jasper, Semrush, Canva, etc.) are built for a US/EU audience and don't reflect GCC business norms, Arabic content needs, or regional buying behavior — true at any company size.
- The founder has an existing distribution channel (an active marketing agency and a large corporate marketing role across multiple business divisions) to reach both SME and larger customers without a cold-start problem.

Note for the developer: selling into larger organizations typically also involves longer procurement cycles, security/compliance questions, and sometimes custom integration requests — worth planning for a more consultative sales process on those accounts even though the product itself serves every size of customer from day one.

3. The Core Problem Being Solved

SME owners are expected to be their own marketer, strategist, copywriter, salesperson, and analyst — with no budget for a team and no time to learn five different tools. AI Business OS compresses that into one guided experience: answer some questions once during onboarding, then let the platform generate the strategy, content, and reporting on an ongoing basis.

4. Revenue Model

- **Subscription SaaS**, billed monthly (target reference price point discussed: \$49/month for Phase 1 — to be validated with real customers before being finalized, alongside a possible tiered structure as the feature set grows).
- Standard SaaS mechanics apply: free trial or demo period, monthly recurring billing, upgrade/downgrade between tiers, cancel anytime.
- Revenue scales by number of subscribed businesses, not by usage — AI API costs are an operating cost line, not something billed per-generation to the customer (at least in Phase 1 pricing).

5. Product Scope

The product has three parts. Working mockups already exist for all three and can be used as the visual/UX reference (landing.html, onboarding.html, dashboard.html, and the combined interactive version app.html).

5a. Marketing website

Public site: hero, features, pricing, sign-up.

5b. Onboarding flow

An 11-step guided questionnaire (serve as prompts to AI) that collects everything the AI needs to personalize the product for that business: company profile, tools/integrations to connect, an automated website scan, marketing goals, business details, brand voice, uploaded business documents, named competitors, and team members. This data becomes the permanent "business profile" the AI references on every future generation.

5c. The application (dashboard + AI tools)

A logged-in web app per company account. Phase 1 ships the full tool set below — built for both SME and larger customers from the start:

- **AI Marketing Planner** — generates a full marketing strategy (audience, positioning, channels, budget allocation, 90-day plan) from the onboarding data. Pure AI generation — no external data source required.
- **CRM & Sales Pipeline** — a built-in CRM to track leads, contacts, deals, and pipeline stages — contacts and companies, deal/opportunity tracking with stages and values, activity/task logging, and a pipeline view (kanban or list). The AI layer surfaces suggested next actions and drafts follow-up messages from pipeline context; the CRM itself is standard structured data (contacts, deals, activities tables) rather than an AI feature.
- **AI Lead Generation / Prospecting** — the customer describes a target (e.g. "companies selling water pumps in Oman" or "construction contractors in Muscat") and the AI compiles a candidate list of companies matching that description, pulling from web search results and public business directories/listings, then extracting company name, website, and public contact details where available. Results are pushed straight into the CRM as new leads. Important sourcing note: this must be built on web search, Google search/maps, and public directory data, not by scraping LinkedIn or other platforms whose terms of service prohibit it — LinkedIn's own Sales Navigator/API program is the compliant path if LinkedIn-sourced data specifically is wanted later. Output quality also depends on how public and indexed the target industry's companies are — expect stronger results for web-visible SMEs than for large private companies with little public footprint.
- **Proposal Generator** — generates client-ready proposals using the business's own uploaded price lists, service descriptions, and brand voice. Requires a document knowledge base (uploaded files are parsed, chunked, and retrieved — a technique called RAG, retrieval-augmented generation — so the AI quotes real prices/services instead of inventing them).
- **Social/content generator** — captions, email copy, content calendar entries. Pure AI generation, same pattern as #1.

- **SEO & keyword tool** — recommends keywords, meta titles/descriptions, and content briefs, using a real keyword-data API (e.g. DataForSEO, Semrush API, or similar) so search volume/difficulty numbers are real, with the AI interpreting and writing around them.
- **Competitor analysis** — the AI compares the customer’s business against named competitors using content fetched from the competitors’ own websites (via the website-scanner component below), surfacing positioning gaps and messaging differences.
- **Social publishing (Meta/Instagram)** — connect and publish/schedule posts directly to Facebook and Instagram via Meta’s Graph API, on top of the content the social/content generator produces.
- **HR policies & SOPs** — AI-generated HR policy and SOP drafts from a library of templates, customized with the business’s details and brand voice.
- **KPI dashboard** — shows real business performance (leads, traffic, conversion, revenue). Pulls real numbers from Google Analytics and Google Search Console via OAuth, plus live figures from the built-in CRM (pipeline value, deals won, lead sources) rather than manual entry.
- **Accounting/payments integration** — connects to accounting software (e.g. QuickBooks, Xero, Zoho Books) so revenue and invoicing figures on the KPI dashboard reflect real financial data, not just marketing metrics.

6. Technical Architecture (What the Developer Needs to Build)

Layer	What it is	Notes
Web application	Public site + authenticated dashboard	Login, permissions, billing screens
Database	Stores companies, users, business profiles, uploaded documents, generated content, subscription status	PostgreSQL (e.g. via Supabase) is a reasonable default
AI API	Generates plans, proposals, content, and interprets SEO/analytics data	Claude or GPT-class API; structured/JSON output preferred so results render as editable UI, not raw text
Document knowledge base (RAG)	Parses uploaded files (price lists, brand guidelines, past proposals) into retrievable chunks	Needed for the Proposal Generator specifically
Website scanner	Crawls the customer’s own site during onboarding to extract content, SEO signals, contact info	Also reusable later for competitor scanning
Google integrations	OAuth connection to Google Analytics Data API + Search Console API + Google Ads API	Core third-party data integration for the KPI dashboard
CRM data layer	Contacts, companies, deals/pipeline stages, activity log — standard relational tables, not an AI feature itself	This is the backbone the AI Lead Generation and KPI dashboard both write into/read from
Lead-sourcing data layer	Web search + public business directories/listings for the AI Lead Generation tool	Avoid platforms whose ToS prohibits scraping (e.g. LinkedIn) — use their official API/partner program instead if needed
Meta integration	OAuth + Graph API for Facebook/Instagram publishing and scheduling	Requires Meta app review and ongoing token/permission management

Accounting integration	Connection to QuickBooks/Xero/Zoho Books (or similar) for real revenue/invoice figures	One provider is enough to start; add others based on customer demand
Payment processing	Recurring subscription billing, invoices, cancellations, failed-payment handling	Needs to support the founder's registered country and international customers
Automation / background jobs	Nightly data refresh, scheduled report generation, reminders, lead-list refresh	Can start simple (e.g. a scheduler like n8n) rather than custom-built

7. Build & Rollout Plan

Validation (before/alongside build)

Manually deliver the core value (a marketing plan, some captions, a proposal) to a handful of real clients using an AI API directly, to confirm the value while the full build is underway.

Phase 1 — Full platform build

Everything in Section 5 and Section 6 above ships as Phase 1: onboarding flow, AI Marketing Planner, CRM & sales pipeline, AI lead generation, proposal generator, social/content generator, SEO tool, competitor analysis, Meta publishing, HR policies/SOPs, KPI dashboard, and accounting integration — built for both SME and larger customers from day one.

Future roadmap

Beyond the Phase 1 scope above: deeper CRM automation (workflow rules, email sequencing), additional accounting/CRM provider options, expansion beyond the initial GCC market, and any integrations customers request once the platform is live.

8. Design & UX Reference

Working front-end mockups already exist and reflect the intended look, flow, and feature set:

- landing.html — marketing site
- onboarding.html — the 11-step onboarding wizard
- dashboard.html — the main application/dashboard
- app.html — all three combined into one clickable interactive prototype

These are visual/interaction references, not production code — the developer should treat them as the UX and content spec to build the real, database-backed application against, not as a codebase to extend directly.

9. Open Items to Finalize With the Developer

- Final tech stack decision (framework, hosting, database provider)
- Exact AI API provider (Claude vs. GPT vs. both) and cost/latency tradeoffs or use our built-in AI agent
- Which keyword-data provider to integrate for the SEO tool
- Payment provider selection (must support the founder's registered country) – TBD between the 3 partners
